

JAVAMS05

Messaging with Cloud Pub/Sub

2 hoursFree

Rate Lab

Overview

In this series of labs, you take a demo microservices Java application built with the Spring framework and modify it to use an external database server. You adopt some of the best practices for tracing, configuration management, and integration with other services using integration patterns.

In this lab, you enhance your application to implement a message handling service with Cloud Pub/Sub so that it can publish a message to a topic that can then be subscribed and processed by other services.

Cloud Pub/Sub is a fully managed, real-time messaging service that enables you to send and receive messages between independent applications. Cloud Pub/Sub brings the scalability, flexibility, and reliability of enterprise message-oriented middleware to the cloud. By providing many-to-many, asynchronous messaging that decouples senders and receivers, Cloud Pub/Sub enables

secure and highly available communication between independently written applications. Cloud Pub/Sub delivers low-latency, durable messaging that helps developers quickly integrate systems hosted on the Google Cloud Platform and externally.

Objectives

In this lab, you learn how to perform the following tasks:

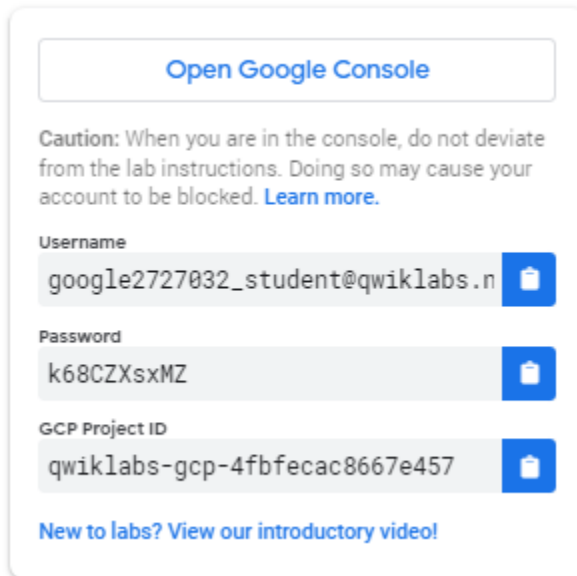

- Enable Cloud Pub/Sub and create a Cloud Pub/Sub topic
- Use Spring to add Cloud Pub/Sub support to your application
- Modify an application to publish Cloud Pub/Sub messages
- Create a Cloud Pub/Sub subscription
- Modify an application to process messages from a Cloud Pub/Sub subscription

Task 0. Lab Preparation

Access Qwiklabs

How to start your lab and sign in to the Console

1. Click the **Start Lab** button. If you need to pay for the lab, a pop-up opens for you to select your payment method. On the left is a panel populated with the temporary credentials that you must use for this lab.

Open Google Console

Caution: When you are in the console, do not deviate from the lab instructions. Doing so may cause your account to be blocked. [Learn more.](#)

Username
google2727032_student@qwiklabs.n 

Password
k68CZXsxMZ 

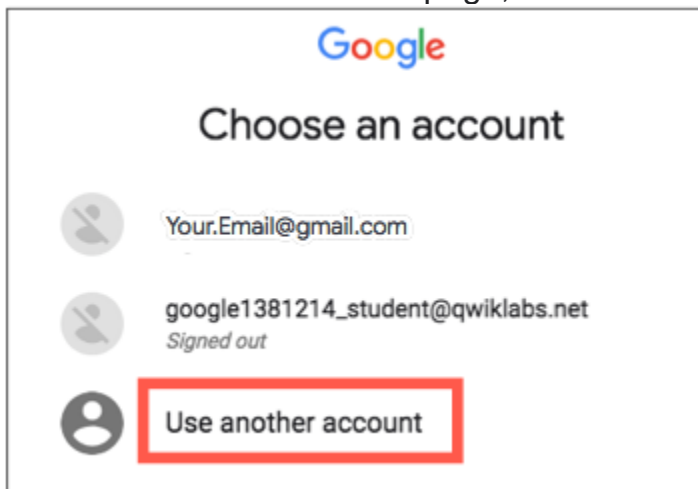

GCP Project ID
qwiklabs-gcp-4fbfecac8667e457 

[New to labs? View our introductory video!](#)

2. Copy the username, and then click **Open Google Console**. The lab spins up resources, and then opens another tab that shows the **Choose an account** page.

Tip: Open the tabs in separate windows, side-by-side.

3. On the Choose an account page, click **Use Another Account**.

Google

Choose an account

 Your.Email@gmail.com

 google1381214_student@qwiklabs.net
Signed out

 **Use another account**

4. The Sign in page opens. Paste the username that you copied from the Connection Details panel. Then copy and paste the password.

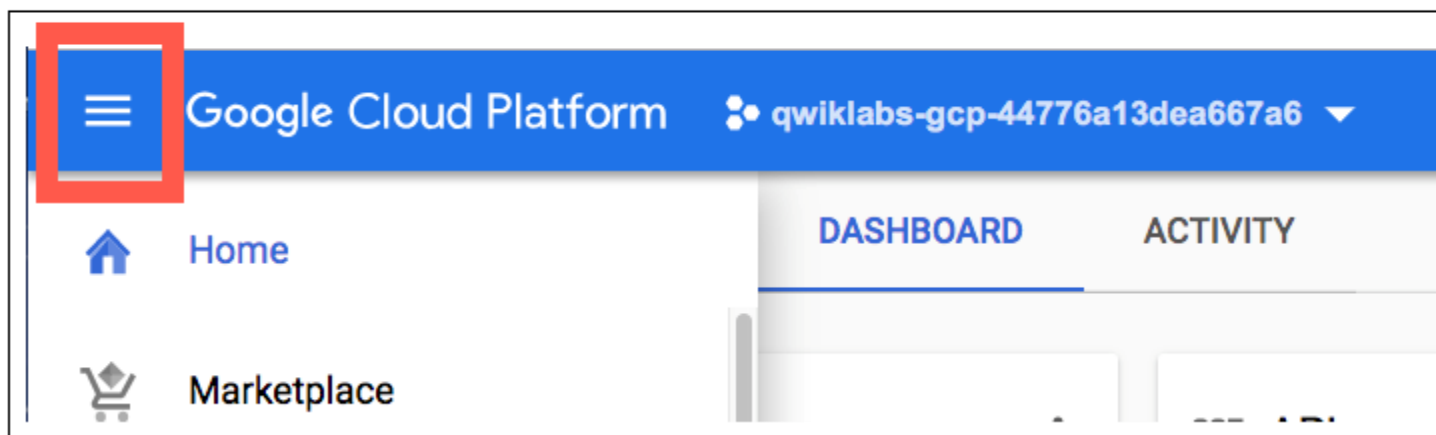

Important: You must use the credentials from the Connection Details panel. Do not use your Qwiklabs credentials. If you have your own GCP account, do not use it for this lab (avoids incurring charges).

5. Click through the subsequent pages:

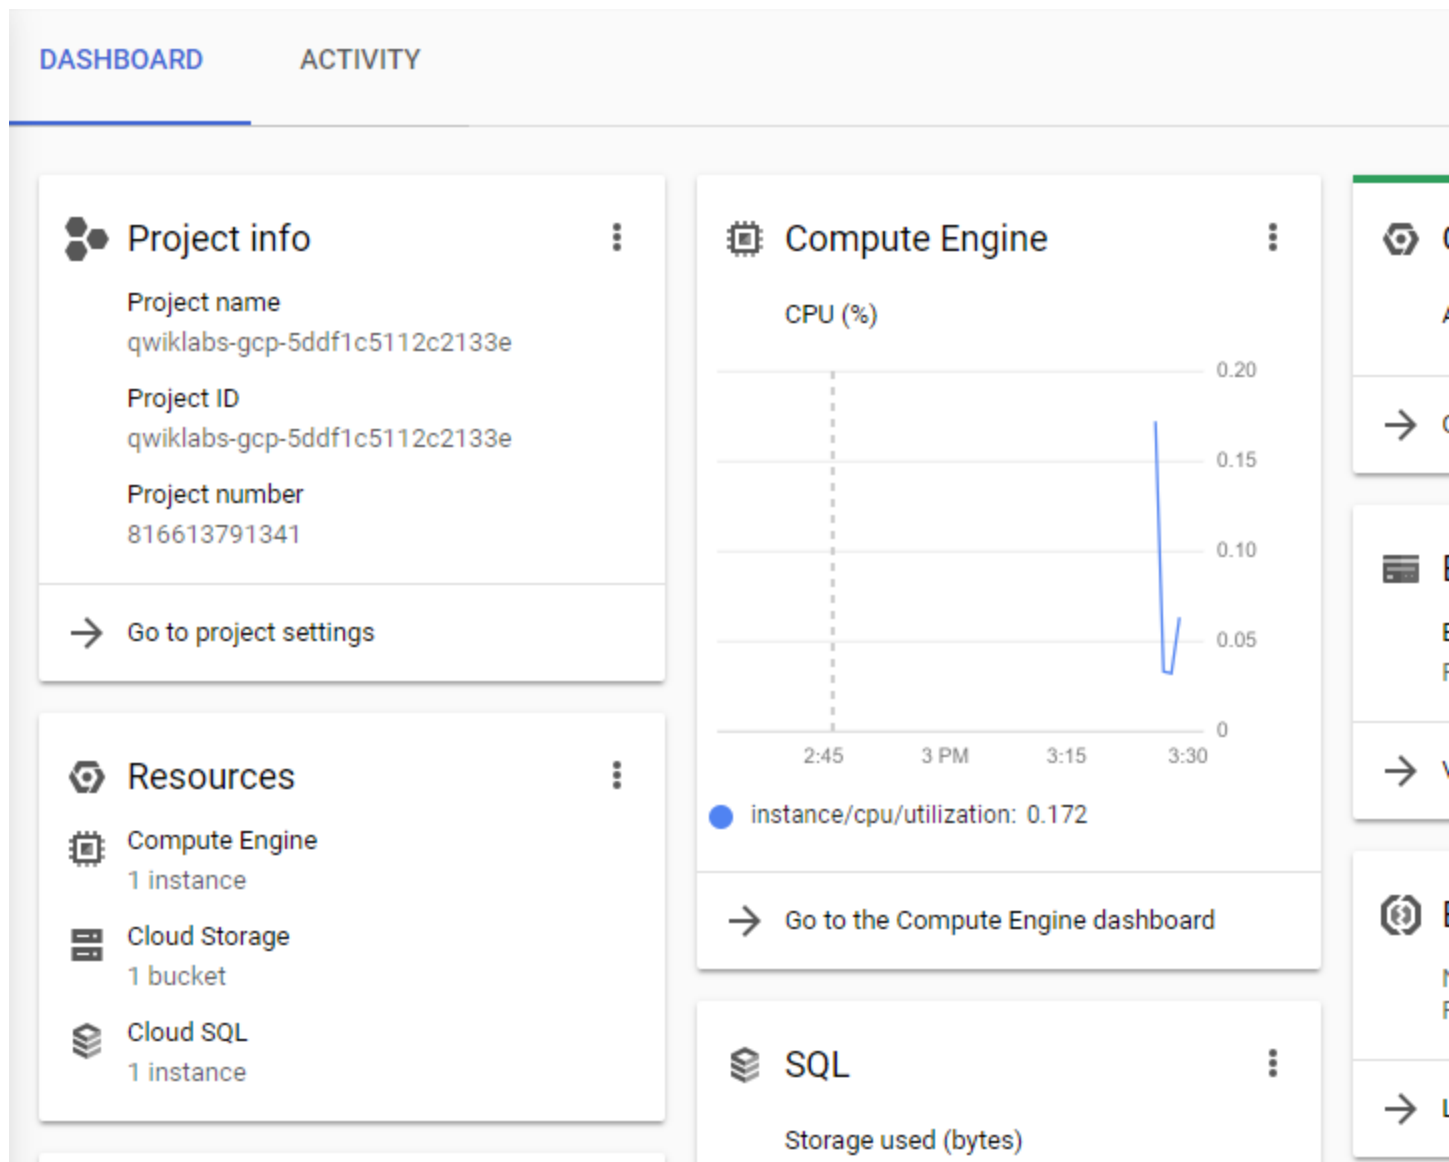

- Accept the terms and conditions.
- Do not add recovery options or two-factor authentication (because this is a temporary account).
- Do not sign up for free trials.

After a few moments, the GCP console opens in this tab.

Note: You can view the menu with a list of GCP Products and Services by clicking the **Navigation menu** at the top-left, next to “Google Cloud Platform”.

After you complete the initial sign-in steps, the project dashboard appears.

Fetch the application source files

The lab setup includes automated deployment of the services that you configured yourself in previous labs. When the setup is complete, copies of the demo application (configured so that they are ready for this lab session) are put into a Cloud Storage bucket named using the project ID for this lab.

Before you proceed with the tasks for this lab, you must first copy the demo application into Cloud Shell so you can continue to work on it.

1. In the upper-right corner of the screen, click **Activate Cloud**

Shell () to open Cloud Shell.

2. Click **Start Cloud Shell**.
3. If **Boost Mode Enabled** is not available (bold), enable boost mode for Cloud Shell.

4. In the Cloud Shell command line, enter the following command to create an environment variable that contains the project ID for this lab:

```
export PROJECT_ID=$(gcloud config list --format 'value(core.project)')
```

5. Verify that the demo application files were created.

```
gsutil ls gs://$PROJECT_ID
```

Repeat the last step if the command reports an error or if it does not list the two folders for the `guestbook-frontend` application and the `guestbook-service` backend application.

Note

A Cloud Storage bucket that is named using the project ID for this lab is automatically created for you by the lab setup. The source code for your applications is copied into this bucket when the Cloud SQL server is ready. You might have to wait a few minutes for this action to complete.

6. Copy the application folders to Cloud Shell.

```
gsutil -m cp -r gs://$PROJECT_ID/* ~/
```

7. Make the Maven wrapper scripts executable.

```
chmod +x ~/guestbook-frontend/mvnw
chmod +x ~/guestbook-service/mvnw
```

8. Click the pencil icon to open the Cloud Shell code editor.

Task 1. Enable Cloud Pub/Sub API

In this task, you enable Cloud Pub/Sub API.

1. In the Cloud Shell enable Cloud Pub/Sub API.

```
gcloud services enable pubsub.googleapis.com
```

Task 2. Create a Cloud Pub/Sub topic

In this task, you create a Cloud Pub/Sub topic to send the message to.

1. Use `gcloud` to create a Cloud Pub/Sub topic.

```
gcloud pubsub topics create messages
```

Task 3. Add Spring Cloud GCP Pub/Sub starter

In this task, you update the guestbook frontend application's `pom.xml` file to include the Spring Cloud GCP starter for Cloud Pub/Sub in the dependency section.

1. In the Cloud Shell code editor, open `~/guestbook-frontend/pom.xml`.
2. Insert the following new dependency at the end of the `<dependencies>` section, just before the closing `</dependencies>` tag:

```
<dependency>
  <groupId>org.springframework.cloud</groupId>
  <artifactId>spring-cloud-gcp-starter-pubsub</artifactId>
</dependency>
```

Task 4. Publish a message

In this task, you use the `PubSubTemplate` bean in Spring Cloud GCP to publish a message to Cloud Pub/Sub. This bean is automatically configured and made available by the starter. You add `PubSubTemplate` to `FrontendController`.

1. Open `guestbook-frontend/src/main/java/com/example/frontend/FrontendController.java` in the Cloud Shell code editor.
2. Add the following statement immediately after the existing `import` directives:

```
import org.springframework.cloud.gcp.pubsub.core.*;
```

3. Insert the following statement between the lines `private GuestbookMessagesClient client;` and `@Value("${greeting:Hello}")`:

```
@Autowired
private PubSubTemplate pubSubTemplate;
```

4. Add the following statement inside the `if` statement to process messages that aren't null or empty, just above the comment `// Post the message to the backend service`:

```
pubSubTemplate.publish("messages", name + ": " + message);
```

The code for `FrontendController.java` should now look like the screenshot:

```
1  package com.example.frontend;
2
3  import org.springframework.stereotype.Controller;
4  import org.springframework.web.client.RestTemplate;
5  import org.springframework.ui.Model;
6  import org.springframework.web.bind.annotation.*;
7  import org.springframework.beans.factory.annotation.*;
8  import java.util.*;
9  import org.springframework.cloud.context.config.annotation.RefreshScope;
10 import org.springframework.cloud.gcp.pubsub.core.*;
11
12 @RefreshScope
13
14 @Controller
15 @SessionAttributes("name")
16 public class FrontendController {
17     @Autowired
18     private GuestbookMessagesClient client;
19     @Autowired
20     private PubSubTemplate pubSubTemplate;
21     @Value("${greeting:Hello}")
22     private String greeting;
23
24     @GetMapping("/")
25     public String index(Model model) {
26         if (model.containsAttribute("name")) {
27             String name = (String) model.asMap().get("name");
28             model.addAttribute("greeting", String.format("%s %s", greeting, name));
29         }
30         model.addAttribute("messages", client.getMessages().getContent());
31         return "index";
32     }
33
34     @PostMapping("/post")
35     public String post(@RequestParam String name, @RequestParam String message, Model model) {
36         model.addAttribute("name", name);
37         if (message != null && !message.trim().isEmpty()) {
38             pubSubTemplate.publish("messages", name + ": " + message);
39             // Post the message to the backend service
40             Map<String, String> payload = new HashMap<>();
41             payload.put("name", name);
42             payload.put("message", message);
43             client.add(payload);
44         }
45         return "redirect:/";
46     }
47 }
--
```

Task 5. Test the application in the Cloud Shell

In this task, you run the application in the Cloud Shell to test the new Cloud Pub/Sub message handling code.

1. In the Cloud Shell change to the `guestbook-service` directory.

```
cd ~/guestbook-service
```

2. Run the backend service application.

```
./mvnw -q spring-boot:run -Dserver.port=8081 -Dspring.profiles.active=cloud
```

The backend service application launches on port 8081. This takes a minute or two to complete and you should wait until you see that the `GuestbookApplication` is running.

```
Started GuestbookApplication in 20.399 seconds (JVM running...)
```

3. Open a new Cloud Shell session tab to run the frontend application by clicking the plus (+) icon to the right of the title tab for the initial Cloud Shell session.

4. Change to the `guestbook-frontend` directory.

```
cd ~/guestbook-frontend
```

5. Start the frontend application with the `cloud` profile.

```
./mvnw spring-boot:run -Dspring.profiles.active=cloud
```

6. Open the Cloud Shell web preview and post a message.

The frontend application tries to publish a message to the Cloud Pub/Sub topic. You will check if this was successful in the next task.

Task 6. Create a subscription

Before subscribing to a topic, you must create a subscription. Cloud Pub/Sub supports pull subscription and push subscription. With a pull subscription, the

client can pull messages from the topic. With a push subscription, Cloud Pub/Sub can publish messages to a target webhook endpoint.

A topic can have multiple subscriptions. A subscription can have many subscribers. If you want to distribute different messages to different subscribers, then each subscriber needs to subscribe to its own subscription. If you want to publish the same messages to all the subscribers, then all the subscribers must subscribe to the same subscription.

Cloud Pub/Sub delivery is "at least once." Thus, you must deal with idempotence and you must deduplicate messages if you cannot process the same message more than once.

In this task, you create a Cloud Pub/Sub subscription and then test it by pulling messages from the subscription before and after using the frontend application to post a message.

1. Open a new Cloud Shell tab.
2. Create a Cloud Pub/Sub subscription.

```
gcloud pubsub subscriptions create messages-subscription-1 \
--topic=messages
```

3. Pull messages from the subscription.

```
gcloud pubsub subscriptions pull messages-subscription-1
```

The `pull messages` command should report 0 items.

The message you posted earlier does not appear, because the message was published before the subscription was created.

4. Return to the frontend application, post another message, and then pull the message again.

```
gcloud pubsub subscriptions pull messages-subscription-1
```

The message appears. The message remains in the subscription until it is acknowledged.

5. Pull the message again and remove it from the subscription by using the auto-acknowledgement switch at the command line.

```
gcloud pubsub subscriptions pull messages-subscription-1 --auto-ack
```

Task 7. Process messages in subscriptions

In this task, you use the Spring `PubSubTemplate` to listen to subscriptions.

1. In the Cloud Shell generate a new project from Spring Initializr.

```
cd ~
curl https://start.spring.io/starter.tgz \
  -d dependencies=cloud-gcp-pubsub \
  -d baseDir=message-processor | tar -xzvf -
```

This command generates a new Spring Boot project with the Cloud Pub/Sub starter preconfigured. The command also automatically downloads and unpacks the project into the `message-processor` directory structure.

2. If you are using the Cloud Shell code editor, select **File > Refresh** to display the new directories and files.
3. Open `~/message-processor/pom.xml` to verify that the starter dependency was automatically added.

```
...
<dependencies>
  <dependency>
    <groupId>org.springframework.cloud</groupId>
    <artifactId>spring-cloud-gcp-starter-pubsub</artifactId>
  </dependency>
  <dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-test</artifactId>
    <scope>test</scope>
  </dependency>
</dependencies>
...
```

4. To write the code to listen for new messages delivered to the topic, open `~/message-processor/src/main/java/com/example/demo/DemoApplication.java` in the Cloud Shell code editor.

5. Add the following `import` directives below the existing `import` directives:

```
import org.springframework.context.annotation.Bean;
import org.springframework.boot.CommandLineRunner;
import org.springframework.cloud.gcp.pubsub.core.*;
```

6. Add the following code block to the class definition for `DemoApplication`, just above the existing definition for the `main` method:

```
@Bean
public CommandLineRunner cli(PubSubTemplate pubSubTemplate) {
    return (args) -> {
        pubSubTemplate.subscribe("messages-subscription-1",
            (msg, ackConsumer) -> {
                System.out.println(msg.getData().toStringUtf8());
                ackConsumer.ack();
            });
    };
}
```

```
}
```

DemoApplication.java should now look like the screenshot:

```
1  package com.example.demo;
2
3  import org.springframework.boot.SpringApplication;
4  import org.springframework.boot.autoconfigure.SpringBootApplication;
5  import org.springframework.context.annotation.Bean;
6  import org.springframework.boot.CommandLineRunner;
7  import org.springframework.cloud.gcp.pubsub.core.*;
8
9  @SpringBootApplication
10 public class DemoApplication {
11
12     @Bean
13     public CommandLineRunner cli(PubSubTemplate pubSubTemplate) {
14         return (args) -> {
15             pubSubTemplate.subscribe("messages-subscription-1",
16                 (msg, ackConsumer) -> {
17                     System.out.println(msg.getData().toStringUtf8());
18                     ackConsumer.ack();
19                 });
20         };
21     }
22
23
24     public static void main(String[] args) {
25         SpringApplication.run(DemoApplication.class, args);
26     }
27 }
```

7. Return to the Cloud Shell tab for the message processor to listen to the topic.

```
cd ~/message-processor
./mvnw -q spring-boot:run
```

8. Open the browser with the frontend application, and post a few messages.
9. Verify that the Cloud Pub/Sub messages are received in the message processor.

The new messages should be displayed in the Cloud Shell tab where the message processor is running, as in the following example:

```
... [main] com.example.demo.DemoApplication : Started
DemoApplication...
Ray: Hey
Ray: Hello!
```

End your lab

When you have completed your lab, click **End Lab**. Qwiklabs removes the resources you've used and cleans the account for you.

You'll be given an opportunity to rate the lab experience. Select the applicable number of stars, type a comment, and then click **Submit**.

The number of stars indicates your rating:

- 1 star = Very dissatisfied
- 2 stars = Dissatisfied
- 3 stars = Neutral
- 4 stars = Satisfied
- 5 stars = Very satisfied

You can close the dialog box if you don't want to provide feedback.

For feedback, suggestions, or corrections, use the **Support** tab.
